Researchers Find Greater Numbers of Neurosurgeons, Neurologists Coincide With Fewer Deaths From Stroke in the United States

CHARLOTTESVILLE, Va. and ROLLING MEADOWS, Ill. (Nov. 30, 2012) — Researchers at Dartmouth-Hitchcock Medical Center in Lebanon, NH, have found an association in the United States between a higher density of neurologists and neurosurgeons and a decreased risk of death from stroke. The findings of their study are described in the article “Association of a higher density of specialist neuroscience providers with fewer deaths from stroke in the United States population. Clinical article,” by Atman Desai, MD, and colleagues, published today online, ahead of print, in the Journal of Neurosurgery (http://thejns.org/doi/full/10.3171/2012.10.JNS12518).

Stroke is a leading cause of death and disability in the United States. Given that neurologists and neurosurgeons are specialists in the field of stroke, the researchers hypothesized that there would be an association between the density of these neuroscience providers and the number of stroke-related deaths.

Desai and colleagues performed a retrospective analysis of data from the Area Resource File 2009–2010, a database containing county-level information on health care facilities and their utilization and expenditures; health care professionals and their training; and socioeconomic and environmental characteristics. Data from 3,141 U.S. counties were analyzed. The primary outcome variable was the average number of deaths from cerebrovascular disease per million population for each county during the three-year period 2004 through 2006. The primary independent variable was the density of neuroscience providers (the combined number of neurologists and neurosurgeons per million population) in 2006.

In the 3,141 U.S. counties that were examined, the median number of deaths from stroke per million persons was 586. The median number of neuroscience providers per county was zero (0).

In an unadjusted analysis, the authors found that an increase of one neuroscience provider per million population was associated with 0.71 fewer deaths due to stroke per million population. In a multivariate analysis, in which adjustments were made for county urbanicity, socioeconomic conditions, and the density of general practitioners, an increase of one neurologist or neurosurgeon was associated with 0.38 fewer deaths from stroke per million population. Curiously, an increase in one general practitioner per million population was associated with 0.143 more stroke deaths in that population. The authors speculate that this may be due to a decreased density of neuroscience providers in counties with high numbers of general practitioners or to increased recruitment of general practitioners to high-risk locales.

The association between the density of neuroscience providers and fewer stroke deaths was present regardless of whether the county was rural or urban. Rural setting was associated with a significant increase in stroke-related deaths, whereas low level of education and persistent poverty were not significant factors.

In an editorial accompanying the article by Desai and colleagues, Fred G. Barker II, MD, FAANS, FACS, states that the most powerful finding of the report is “the much higher stroke-related mortality for rural residents.” Barker points out the time-sensitive nature of stroke treatment and the lack of sophisticated stroke care in many areas. Of the 3,141 counties listed in the Area Resource File, 2051 are classified as rural. Neurosurgeons are generally clustered in and around cities.
that house tertiary care hospitals, and thus there is large disparity in the density of neuroscience providers throughout U.S. counties. Desai and colleagues state that timely diagnosis and intervention depend on the immediate availability of both specialties, and this is extremely important in cases of stroke.

Given the association found between the distribution of neuroscience providers and stroke-related deaths, Desai and colleagues conclude that the availability of local neurologists and neurosurgeons may be important for the overall likelihood of surviving a stroke, and thus specialist education and practice throughout the U.S. should be promoted.

For 68 years, the Journal of Neurosurgery has been recognized by neurosurgeons and other medical specialists the world over for its authoritative, clinical articles, cutting-edge laboratory research papers, renowned case reports, expert technical notes, and more. Each article is rigorously peer reviewed. The Journal of Neurosurgery is published monthly by the JNS Publishing Group, the scholarly journal division of the American Association of Neurological Surgeons (http://www.AANS.org), an association dedicated to advancing the specialty of neurological surgery in order to promote the highest quality of patient care. The Journal of Neurosurgery appears in print and on the Internet (http://www.thejns.org).

Founded in 1931 as the Harvey Cushing Society, the American Association of Neurological Surgeons (AANS) is a scientific and educational association with more than 8,200 members worldwide. The AANS is dedicated to advancing the specialty of neurological surgery in order to provide the highest quality of neurosurgical care to the public. All active members of the AANS are certified by the American Board of Neurological Surgery, the Royal College of Physicians and Surgeons (Neurosurgery) of Canada or the Mexican Council of Neurological Surgery, AC.

Neurological surgery is the medical specialty concerned with the prevention, diagnosis, treatment and rehabilitation of disorders that affect the entire nervous system including the spinal column, spinal cord, brain and peripheral nerves. For more information, visit www.AANS.org.
