www.neurotraumasection.org
Introduction

As the number of people infected with the novel coronavirus rapidly increases, some neurosurgeons are being asked to participate in the care of critically ill patients, even those without neurological involvement. This presentation is meant to be a basic guide to help neurosurgeons achieve this mission.
Disclaimer

• The protocols discussed in this presentation are from the Mission: Possible program at University Hospitals of Cleveland, based on guidelines and recommendations from several medical societies and the Centers for Disease Control (CDC).

• Please check with your own hospital or institution to see if there is any variation from these protocols before implementing them in your own practice.
Disclaimer

The content provided on the AANS and CNS websites, including any affiliated AANS/CNS section website (collectively, the “AANS/CNS Sites”), regarding or in any way related to COVID-19 is offered as an educational service. Any educational content published on the AANS/CNS Sites regarding COVID-19 does not constitute or imply its approval, endorsement, sponsorship or recommendation by the AANS or CNS. The content should not be considered inclusive of all proper treatments, methods of care, or as statements of the standard of care and is not continually updated and may not reflect the most current evidence. Nothing in the educational content published on the AANS/CNS Sites should be considered, or used as a substitute for, medical advice, diagnosis or treatment. The AANS/CNS Sites and the educational services offered therein do not constitute the practice of medicine or any medical or other professional health care advice, diagnosis or treatment. The AANS and CNS assume no responsibility for any injury or damage to persons or property arising out of or related to any use of this content or for any errors or omissions.
COVID-19

- Coronavirus disease 2019 (COVID-19) is a respiratory tract infection caused by a newly emergent coronavirus, SARS-CoV-2, that was first recognized in Wuhan, China, in December 2019.

- Genetic sequencing of the virus suggests that SARS-CoV-2 is a betacoronavirus closely linked to the SARS.
Personal Protective Equipment

When taking care of COVID-19 patients, please adhere to all of your institution’s policies regarding personal protective equipment (PPE)

To help others, you must stay healthy yourself!

Organ System Interactions

While this guide focuses on organ pathophysiology and treatment, it should be remembered that each organ system interacts with the others. Sometimes the best treatment of one organ is detrimental to another. It is always important to do what is best for the whole organism, not just one organ.
Organ System Interactions

For example, consider a patient with systolic heart failure with pulmonary edema and hypoxic respiratory failure who also has an acute kidney injury with oliguria. While the best treatment for the hypoxia might be diuresis to reduce the pulmonary edema, this could worsen the kidney injury and push this patient into renal failure with the need for dialysis. This would decrease the chances of recovery. A better strategy might to be to increase PEEP to improve oxygenation while the kidney injury resolves.
COVID-19 Infection in ICU

In addition to the hypoxic respiratory failure, several organ and physiologic derangements are observed.

- Marked increase in acute phase reactants
- Venous thromboembolic disease
- Hemodynamic instability
- Cardiac Dysfunction
- Acute Kidney Injury
COVID-19 - Hematologic Profile

- Several pro-coagulant factors are increased
  - Factor VIII
  - VWF
  - Fibrinogen known to be associated with an increased risk of thrombosis

- Increased D-Dimer suggestive of local ongoing fibrinolysis

- Normal platelet counts
- Normal PT and PTT

No DIC
Venous Thromboembolic Disease

Common in the ICU population

- Immobility
- Prothrombotic conditions
  - Reports of higher rates of thrombosis with COVID-19

Conditions

- Deep vein thrombosis (DVT)
- Pulmonary embolism (PE)
- Sagittal sinus thrombosis
## DVT Risk Assessment

**VENOUS THROMBOEMBOLISM RISK ASSESSMENT AND PROPHYLAXIS GUIDELINE FOR ADULT PATIENTS**

### Risk assessment methods
- Each factor listed with a point score
- Add points based on factor(s) to determine risk factor score
- Choose recommended prophylaxis based on total score in conjunction with clinical judgment

### Factors

### Total risk factor score

TOTAL POINTS: □

POINTS
Usual VTE Prophylaxis

- Most ICU patients will be high risk

- **HIGHEST RISK (≥ 5 or more points)**
  - One pharmacologic option AND intermittent pneumatic compression
  - Use nonpharmacologic options as sole prophylaxis for patients not candidates for anticoagulant therapy
    - Enoxaparin 40 mg SC daily
    - Enoxaparin 30 mg SC daily if CrCl < 30 mL/min AND not on dialysis
    - Unfractionated heparin 5,000 units SC Q8H
    - Fondaparinux 2.5 mg SC daily
    - Intermittent pneumatic compression

- **BMI ≥ 40 kg/m²**
  - One pharmacologic option AND intermittent pneumatic compression
  - Use nonpharmacologic options as sole prophylaxis for patients not candidates for anticoagulant therapy
    - Enoxaparin 40 mg SC Q12H (if BMI ≥ 40 – 49.9 kg/m²)
    - Enoxaparin 60 mg SC Q12H (if BMI ≥ 50 kg/m²)
    - Unfractionated heparin 7,500 units SC Q8H
    - Fondaparinux 2.5 mg SC daily
    - Intermittent pneumatic compression
VTE Prophylaxis

Prophylaxis may be held for high risk of bleeding

- Ongoing or recent severe hemorrhage
- Thrombocytopenia (platelets <100,000)
- Renal failure, end stage liver disease
- Coagulopathy
- Currently on anticoagulation therapy
COVID-19 Venous Thromboembolic Disease

- Standard prophylaxis is not adequately preventing thromboembolic events
- Several reports
  - Pulmonary embolism
  - Arterial thrombosis
  - Strokes
  - Thrombosis in unusual areas
  - Microthrombi in lungs on autopsy series

J Thromb Haemost. April 2020
**VTE Prophylaxis in COVID-19 Patients**

**STEP I – Calculate DIC Score**

<table>
<thead>
<tr>
<th>ISTH Criteria for DIC - 5 points are needed for DIC Diagnosis</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Platelets</strong></td>
</tr>
<tr>
<td></td>
</tr>
<tr>
<td><strong>D-Dimer</strong></td>
</tr>
<tr>
<td></td>
</tr>
<tr>
<td><strong>Fibrinogen</strong></td>
</tr>
<tr>
<td><strong>Prolonged PT</strong></td>
</tr>
<tr>
<td></td>
</tr>
</tbody>
</table>

If score is ≥ 5 – DIC is diagnosed – hematology consult

If score is < 5 – there is no DIC – proceed to STEP II

**STEP II – POC ultrasound of lower extremities**

- DVT present – full anticoagulation
- NO DVT – proceed to STEP III

University Hospitals COVID-19 DVT prophylaxis protocol
### STEP III - VTE prophylaxis

<table>
<thead>
<tr>
<th>D-Dimer ng/ml</th>
<th>Weight (kg)</th>
<th>Drug target Heparin Assay, Lovenox is 0.2 – 0.4 IU/mL</th>
</tr>
</thead>
<tbody>
<tr>
<td>&lt; 1000</td>
<td>&lt; 100</td>
<td>Enoxaparin 40 mg qd</td>
</tr>
<tr>
<td></td>
<td>100-150</td>
<td>Enoxaparin 40 mg bid</td>
</tr>
<tr>
<td></td>
<td>&gt; 150</td>
<td>Enoxaparin 60 mg bid</td>
</tr>
</tbody>
</table>

- Enoxaparin should be timed for 0900 (and 2100 if BID)
- **Heparin Assay, Lovenox should be drawn 4 hours after the second dose, then as needed based on level and renal function**
  - Adjust doses in increments of 10 – 20 mg depending on level and renal function
  - If on CRRT or HD,
    - use heparin 5,000 Units Q8H when weight < 150 Kg
    - use heparin 7,500 Units Q8H when weight > 150 Kg

<table>
<thead>
<tr>
<th>D-Dimer ng/ml</th>
<th>Weight (kg)</th>
<th>Drug target Heparin Assay, Lovenox is 0.2 – 0.4 IU/mL</th>
</tr>
</thead>
<tbody>
<tr>
<td>1000 – 3000</td>
<td>&lt; 100</td>
<td>Enoxaparin 40 mg bid</td>
</tr>
<tr>
<td></td>
<td>100-150</td>
<td>Enoxaparin 80 mg bid</td>
</tr>
<tr>
<td></td>
<td>&gt; 150</td>
<td>Enoxaparin 120 mg bid</td>
</tr>
</tbody>
</table>

- For doses ≥ 80 mg, may need to use the “Exoxaparin Therapeutic Anticoagulation” UHCare orderset for ease of ordering higher doses
- Enoxaparin should be timed for 0900 and 2100
- **Heparin Assay, Lovenox should be drawn 4 hours after the second dose, then as needed based on level and renal function**
  - Adjust doses in increments of 10 – 20 mg depending on level and renal function
  - If on CRRT or HD, use low intensity unfractionated Heparin drip

<table>
<thead>
<tr>
<th>D-Dimer ng/ml</th>
<th>Weight (kg)</th>
<th>Drug target Heparin Assay, 0.4 – 0.7 IU/ml</th>
</tr>
</thead>
<tbody>
<tr>
<td>&gt; 3000</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

- In absence or renal failure and morbid Obesity use Enoxaparin 1 mg/Kg every 12 hr
- **OR**
- Start with Hi intensity unfractionated Heparin drip – as per EMR
- If no improvement in D-Dimer in 24-48 consult hematology and/or vascular medicine
# Pulmonary Embolism (PE): Definitions

<table>
<thead>
<tr>
<th>Massive PE</th>
<th>Submassive PE</th>
<th>Minor/Nonmassive PE</th>
</tr>
</thead>
<tbody>
<tr>
<td>High risk</td>
<td>Moderate/intermediate risk</td>
<td>Low risk</td>
</tr>
<tr>
<td>• Sustained hypotension (systolic BP &lt;90 mmHg for ≥15 min)</td>
<td>• Systemically normotensive (systolic BP ≥90 mmHg)</td>
<td>• Systemically normotensive (systolic BP ≥90 mmHg)</td>
</tr>
<tr>
<td>• Inotropic support</td>
<td>• <strong>RV dysfunction</strong></td>
<td>• No RV dysfunction</td>
</tr>
<tr>
<td>• Pulseless</td>
<td>• Myocardial necrosis</td>
<td>• No myocardial necrosis</td>
</tr>
<tr>
<td>• Persistent profound bradycardia (HR &lt;40 bpm with signs or symptoms of shock)</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

**RV dysfunction suspected**
- RV/LV ratio > 0.9 or RV systolic dysfunction on echo
- RV/LV ratio > 0.9 on CT
- Elevation of BNP (>90 pg/mL)
- Elevation of NTpro-BNP (>500 pg/mL)
- ECG changes:
  - new complete or incomplete RBBB
  - anteroseptal ST elevation or depression
  - anteroseptal T-wave inversion

**Physiologic Effects of PE**

- **Impaired gas exchange in all types**
  - V/Q mismatch, elevated A-a gradient
  - hypercapnia usually not present
  - functional shunting

- **Hypotension in massive or submassive PE**
  - decreased pre-load, if RV can’t manage
  - increased pulmonary vascular resistance
  - RV strain (seen on EKG or echo)
  - Rise in troponin and BNP reflect the degree of RV injury. Lactic acidosis reflect severity of shock
Diagnosis of Pulmonary Embolism

- Evaluate hypoxia
  - Chest x-ray to look for parenchymal disease that may explain hypoxemia
  - Arterial blood gas to evaluate A-a gradient
- Spiral contrasted chest CT
- **Cannot perform V/Q scan** because of risk of viral spread from inhaled tracer
Treatment of PE

- ABC’s always
- Fluids, pressors, ventilator management
  - hydration sparingly, can worsen right heart strain
  - avoid tachycardia, can worsen hypotension
    - further decrease in pre-load
  - be careful with plateau pressures
- PE Response Team (PERT) if available at your institution to navigate for the optimal therapeutic intervention
Pulmonary Embolism Treatment

- **Anticoagulation**
  - Goal PTT 50-70
  - Goal Factor Xa 0.3-0.8
  - Goal INR 2-3

- IVC filter to prevent subsequent PE if anticoagulation is not an option

- For massive PE or if anticoagulation is contraindicated
  - Thrombectomy – by cardiac catheterization or surgical
  - Systemic Thrombolysis: for life-threatening PE
    - 50 mg i.v., may repeat x1
  - Catheter directed thrombolysis
Hemodynamic Instability

- **Distributive**
  - Sepsis
  - Anaphylaxis
  - Spinal

- **Cardiogenic**
  - Myocardial Infarct
  - Heart Failure
  - Valve D/O

- **Hypovolemic**
  - Hemorrhage
  - Trauma
  - Dehydration

- **Obstructive**
  - Pulmonary Embolism
  - Cardiac Tamponade

- **Tissue Hypoperfusion**
- **Tissue Hypoxemia**
- **Anaerobic Metabolism**
- **Lactic Production**
- **End-Organ Injury**
- **Multi-System Organ Dysfunction**
Oxygen Delivery

\[ DO_2 = CaO_2 \times CO \]

**In Shock**
**Optimize**
**DO2**

- \( CaO_2 \)
  - \( PaO_2 \)
  - \( SaO_2 \)
  - \( Hgb \)
- **Cardiac Output**
  - Heart Rate
  - Stroke Volume
  - Preload
  - Afterload
  - Contractility
    - CVP
    - PCWP
    - PVR
    - SVR
    - EF%
Stepwise Approach to Evaluate Shock

- Step 1: Clinical assessment
- Step 2: Volume status
- Step 3: Preload and fluid responsiveness
- Step 4: Cardiac output
- Step 5: Cardiac contractility
- Step 6: Differentiate shock state
Hemodynamic Goals in COVID-19

- Goal is euvolemia – WHO and ARDSnet recommended FACTT Algorithm
- Attempt de-resuscitation within 24-48 hours of achieving stability
- Point of care ultrasound of IVC and cardiac output maybe utilized in selected patients
- Pharmacy to concentrate all i.v. medications
- Enteral fluids to be determined on case by case basis by intensivist
Normal Cardiac Parameters

- Cardiac Output (CO = HR x stroke volume)
  Normal 4-8 L/min

- Cardiac Index (CI = CO/body surface area)
  Normal 3-5 L/min/m\(^2\)

- CVP
  Normal 1-6 mm Hg

- Pulmonary artery pressure
  Normal 16-24/5-12 mmHg
Hemodynamic Monitoring

- **Echocardiogram**
  - Heart chamber morphology and contractility (ejection fraction)
  - Cardiac valve function
  - Vena cava collapse (sign of hypovolemia)
  - Estimates pulmonary artery pressure (may relate left ventricular filling and subsequently cardiac output)

- **Central venous catheter**
  - Central venous pressure

- **Pulmonary artery catheter (Swan-Ganz)**
  - **Not for routine use.** Reserve for patients with Pulmonary HTN and advanced heart failure
  - Measures right ventricular pressures
  - Measures PA wedge pressure
  - Estimates cardiac output

CO indicates cardiac output; CS, cardiogenic shock; PD-3, phosphodiesterase-3; PVR, pulmonary vascular resistance; and SVR, systemic vascular resistance.
Sepsis – 3 Clinical Identification

- Outside ICU - Known or presumed active infection who are likely to have poor outcomes can be identified by Sequential Organ Failure Assessment (SOFA)
  - SBP <100 mmHg
  - RR > 22
  - Altered mental status (encephalopathy)

- ICU patients with suspected or presumed infection who are likely to have poor outcomes can be identified by 2 or more SOFA points

- Septic shock
  - Despite adequate fluid resuscitation pressors are needed to maintain MAP > 65 \text{ AND}\n  - Serum Lactate > 2 mmol/L

© 2017 SCCM and EICM
2016 Sepsis Guidelines

- Obtain cultures before starting antibiotics
- Start broad-spectrum i.v. antibiotics within one hour
- Volume resuscitation with i.v. crystalloids > 30 mL/kg within the first 3 hours
  - Administration of balanced crystalloids has a favorable effect on the composite of death, new RRT, and persistent renal impairment
- Colloid fluids may also be given if large amounts of crystalloids are being used
Treatment of Septic Shock

- Initial target **MAP >65 mmHg** in patients with septic shock requiring vasopressors
- **Norepinephrine** is the first choice vasopressor for septic shock
- **Vasopressin** or epinephrine may be added if necessary
Treatment of Septic Shock

- Hemodynamic/cardiac assessment may be necessary (echo, cardiac output monitoring) if clinical examination does not reveal the cause of the shock.
- Hydrocortisone – stress dose may be used as a supplement to pressors.
- Lactate measurement can be used to guide extent of resuscitation with the goal of returning to normal lactate levels.
Cardiogenic Shock

- Hypotension secondary to decreased cardiac output
- Must ensure that there is no hypovolemia and optimal cardiac perfusion
- May require inotropic agent to promote contraction e.g. dobutamine
- Mechanical support (LVAD, aortic balloon pump, etc.) for refractory cases
Stress Cardiomyopathy

- Catecholamine-induced cardiac injury
  - Takotsubo cardiomyopathy
- Dilation of cardiac apex, LV outflow obstruction
- Reversible, support until recovery
Hypovolemic Shock

Causes:

- Hemorrhage
- Fluid loss (gastric fluid, diarrhea, burns)
- Interstitial fluid accumulation (third spacing)

- **Volume resuscitation** with crystalloids
  - Whole blood may be considered in the case of significant anemia
Anemia and Transfusion

- Evaluate for active bleeding
  - GI: varices, ulcers, hemorrhoids, etc.
  - Procedure-related (retroperitoneal, hemothorax)

- Reversible causes
  - Check iron, vitamin $B_{12}$, folate levels
  - Marrow-suppressing medications

- Transfuse packed rbc’s for Hb<7 g/dL
  - May consider whole blood for severe hypovolemic shock

NEJM 1999 Feb 11;340(6):409-17
COVID-19 Cardiac Involvement

- Mechanism of injury is unclear
- High troponin levels are associated with poor prognosis
- Current observations include:
  - Diffuse LV dysfunction
  - Cardiogenic shock related to cytokine storm
  - Fatal arrhythmias
  - Pericardiomyocarditis
Congestive Heart Failure

- Cardiac dysfunction resulting in reduced cardiac output and/or elevated intracardiac pressures
- May be from impairment of either systolic or diastolic function
Diastolic Failure

- During diastole, the atria of the heart contract, filling the ventricles
- Decreased cardiac compliance, impaired atrial contractility, or tricuspid/mitral valve stenosis may result in poor filling
- Heart becomes pre-load dependent
- Patients may benefit from higher CVP (8-12 mmHg) to optimize cardiac filling
  - May give fluids to increase filling pressures
Systolic Failure

- During systole, ventricular contraction pumps blood into the pulmonary artery and aorta.
- Poor ventricular contraction, tricuspid/mitral valve regurgitation, pulmonic/aortic valve stenosis can result in poor ventricular output.
- LV ejection fraction $\leq 40\%$.
Systolic Failure

- Heart becomes afterload sensitive
- Patients may benefit from afterload reduction
  - Traditional diuretics (Loop diuretics)
  - ACE inhibitors
  - Direct vasodilators: hydralazine in combination with nitrates for patients with renal pathology
- Patients with hypotension may require positive inotropic agent +/- pressor
Tachycardia

- Sinus tachycardia
  - Common causes include hypovolemia/hypotension, hypoxia, PE, and pain
  - Address underlying condition
- Narrow Complex (QRS ≤ 120ms)
  - Atrial fibrillation/flutter
  - Re-entrant tachycardia
- Wide Complex (QRS ≥ 120ms)
  - Ventricular tachycardia until proven otherwise
Atrial Fibrillation

- Common cause of tachycardia in the ICU
- May have rapid ventricular response (HR>120)
- Look for exacerbating factors such as volume overload causing atrial stretching, hyperthyroidism, electrolyte abnormalities
- May cause hypotension as rapid heart rate can decrease filling time and subsequently stroke volume
- Initiate treatment to identify and control the precipitating factor then control HR
Acute Medical Treatment of RVR

- Selective $\beta_1$ antagonists
  - Metoprolol 5 mg i.v. over 1-2 minutes, may be repeated x2
- Calcium channel antagonist – like Diltiazem or Verapamil if LV systolic function is normal
- Patients may require drips of $\beta$-blocker or calcium channel blocker (see Appendix 1)
- Amiodarone drip for refractory RVR
- When SVT is suspected Adenosine can be used
  - Causes transient cardiac pause
  - 6 mg i.v. push. If no response repeat at 12 mg i.v. push.
Ventricular Tachycardia

- Sustained Monomorphic Ventricular Tachycardia
  - Unstable = Cardioversion and ACLS
  - Stable
    - Related to structural heart disease
      - Amiodarone then cardioversion if not terminated
    - Idiopathic
      - Verapamil if history of verapamil sensitive VT
      - β-blockers for outflow track VT

- Cardiology consult for further support
Acute Coronary Syndrome

Constellation of clinical symptoms compatible with acute myocardial ischemia

• ST-segment elevation MI (STEMI): coronary occlusion resulting in transmural ischemia

• non-ST-segment elevation MI (NSTEMI): Partial coronary obstruction resulting in subendocardial ischemia

• unstable angina: pain at rest or with minimal exertion, crescendo pattern
General Measures for MI

- Optimize oxygen delivery
- Obtain EKG, ensure electrolytes are within normal limits
- Decrease cardiac workload
  - β-blocker to decrease cardiac wall stress and heart rate
  - Make sure the patient is adequately resuscitated as decrease in heart rate may result in decreased cardiac output in the setting of hypovolemia
- Serial troponin levels
- Echocardiogram
Treatment of STEMI

- Percutaneous coronary intervention
- Fibrinolytic therapy for cases where PCI cannot be performed in a timely fashion
Treatment of NSTEMI/UA

- Antiplatelet therapy
  - aspirin
  - clopidogrel
  - glycoprotein 2b/3a inhibitors

- β-blockers, ACEIs, statins

- Avoid calcium channel blockers in the acute setting
Acute Kidney Injury and Renal Failure

1. Filtration
2. Reabsorption
3. Secretion
4. Excretion

Glomerular capillaries
Bowman's capsule
Peritubular capillaries
Renal vein
RIFLE Criteria

Oliguria: urine output less than 0.5 ml/kg/hr

Developed by the Acute Dialysis Quality Initiative (ADQI)
Acute Kidney Injury Network (AKIN)

Kidney International Suppl 2012; 2(1)
Acute Kidney Injury Network (AKIN)

- Does not require known historical creatinine
- Only considered after adequate volume resuscitation
- Post-renal obstruction has been ruled out

Kidney International Suppl 2012; 2(1)
Pre-Renal AKI

Intravascular volume depletion
Decreased effective volume
- CHF
- Hypovolemia and dehydration
- Cirrhosis
- Early sepsis
- Renal vasoconstriction

Selective ischemia- renal artery stenosis
Diagnosis of Pre-Renal AKI

- Urine specific gravity > 1.020
- FeNa < 1%
- Urine osmolarity > 350
Etiology of (intra-renal) AKD
and Typical* Urinalysis Findings

Acute Tubular Necrosis (ATN) [~ 90% of AKD cases]
  • urine sediment benign, mild proteinuria/hematuria
  • muddy-brown casts

Allergic Interstitial Nephritis
  • urine eosinophils
  • variable urine sediment, proteinuria and hematuria

Rhabdomyolysis
  • brown urine, dip stick (+) blood but RBC (-) by microscopy
  • myoglobin (+)

Glomerulonephritis
  • marked proteinuria
  • RBC casts (highly specific)

* urinalysis is often non-diagnostic
Acute Tubular Necrosis

Death of renal tubular cells

- Hypotension/hypoxia
- Rhabdomyolysis
- Cytotoxic drugs
- Aminoglycosides
- Blood transfusion reactions

Usually reversible if underlying cause is remedied
Prevention

- Maintain hydration (isotonic i.v. fluids)
- Reducing risk from nephrotoxins
  - Single vs. multiple daily doses of aminoglycosides
  - Lipid complex vs. standard amphotericin
  - Iso-osmotic vs. standard or “low” osmolality radiocontrast media
- Maintain perfusion pressure
# Acute Kidney Injury

## High Risk

</tbody>
</table>

- Discontinue all nephrotoxic agents when possible
- Ensure volume status and perfusion pressure
- Consider functional hemodynamic monitoring
- Monitor Serum creatinine and urine output
- Avoid hyperglycemia
- Consider alternatives to radiocontrast procedures
  - Non-invasive diagnostic workup
  - Consider invasive diagnostic workup
    - Check for changes in drug dosing
    - Consider Renal Replacement Therapy
    - Consider ICU admission
    - Avoid subclavian catheters if possible

*Kidney International Suppl 2012; 2(1)*
Treatment of AKI

- Avoid or minimize exposure to nephrotoxic agents
- Diuretics only used to treat volume overload
  - Have no impact on recovery or prognosis
- Use crystalloids for volume expansion except in cases of hypovolemic shock
- Vasopressors may be used in conjunction with fluid resuscitation in cases of vasomotor shock
- Do not use low-dose dopamine
Indications For Dialysis

- Life-threatening conditions
  - Acute pulmonary edema from volume overload
  - Electrolyte Imbalance
    - Hyperkalemia
    - Hyponatremia
    - Increased calcium phosphate product
  - Uremia
    - Encephalopathy
    - Pericarditis
    - Intractable nausea and vomiting
  - Acidosis
Palliative Care

Ultimately, the goal of treatment is to facilitate a patient’s recovery to a condition that the patient would find acceptable. If this cannot be achieved, limitations of care should be discussed with the patient and the patient’s family.

A provider may choose to withhold a therapy if it is believed to be futile in the care of the patient.
Palliative Care

Limitations of care may include (but are not limited to):

- **DNR Arrest**
  - Pursue all care unless patient suffers a cardiac arrest

- **DNI**
  - Do not intubate

- **DNR Comfort Care**
  - Withdraw supportive measures
  - Patient’s comfort becomes the highest priority
Palliative Care

May consider specific therapies individually:

- Dialysis
- Vasopressors
- Antibiotics
- Procedures
  - Tracheostomy
  - Percutaneous gastostomy/feeding tube
  - Vascular access
Palliative Care – ICU Triggers

- SNF patient with poor performance status
- Advanced dementia
- Age over 80 – all COVID +
- Age over 70 + 1 advanced organ system disease – ESRD, $O_2$-dependent COPD, Stage C/D CHF, Childs B/C cirrhosis
- Metastatic malignancy
- Advanced organ system disease
  - ESRD
  - $O_2$ dependent COPD
  - Advanced CHF
  - Child B/C cirrhosis
- Worsening clinical course on mechanical ventilation
- Shock state needing pressors for more than 2 days
The End

Remember:
Follow your local protocols
Stay safe and healthy

* = High concentration drips available for patients with high dose requirements, call local pharmacy for assistance.

RDOS = Respiratory Distress Observation Scale

Separate dosing regimens available for Chronic Pain and Status Epilepticus, Depression and Migraine.
Appendix 3: Surviving Sepsis Campaign: Guidelines for the Management of COVID-19

I. Infection Control
- For aerosol-generating procedures, use fitted respirator masks (N95 respirators, FFP2, or equivalent) (best practice).
- Perform aerosol-generating procedures in negative pressure room (best practice).
- For usual care for non-ventilated patients, use surgical/medical masks (weak recommendation).
- For non-aerosol-generating procedures on ventilated patients, use surgical/medical masks (weak recommendation).
- For intubation, use video-guided laryngoscopy over direct laryngoscopy (weak recommendation).
- Intubation should be performed by provider most experienced with airway management (best practice).

II. Laboratory Diagnosis and Specimens
- For intubated and mechanically ventilated adults:
  - Obtain lower respiratory tract over nasopharyngeal/oropharyngeal samples (weak recommendation).
  - Obtain endotracheal aspirates over bronchial wash/bronchoalveolar lavage samples (weak recommendation).
Appendix 3: Surviving Sepsis Campaign: Guidelines for the Management of COVID-19

III. Supportive Care

- Use dynamic parameters, skin temperature, capillary refilling time, and/or serum lactate over static parameters to assess fluid responsiveness (weak recommendation).
- Use conservative over liberal fluid strategy (weak recommendation).
- Use crystalloids over colloids (strong recommendation).
- Use buffered/balanced crystalloids over unbalanced crystalloids (weak recommendation).
- Do not use hydroxyethyl starches (strong recommendation).
- Do not use gelatins (weak recommendation).
- Do not use dextrose (weak recommendation).
- Do not routinely use albumin for initial resuscitation (weak recommendation).
- Use norepinephrine as first-line vasoactive agent (weak recommendation).
- If norepinephrine not available, use vasopressin or epinephrine (weak recommendation).
- Do not use dopamine if norepinephrine is available (strong recommendation).
- Add vasopressin as second-line agent if target MAP can’t be achieved by norepinephrine alone (weak recommendation).
- Titrate vasoactive agents to target MAP of 60-65 mmHg (weak recommendation).
- For cardiac dysfunction and persistent hypoperfusion despite fluid resuscitation and norepinephrine, add dobutamine (weak recommendation).
- For refractory shock, use low-dose corticosteroid therapy (weak recommendation).
- Start supplemental O2 if SPO2 is < 92% (weak recommendation) and if SPO2 is < 90% (strong recommendation).
Appendix 3: Surviving Sepsis Campaign: Guidelines for the Management of COVID-19

- Maintain SPO2 no higher than 96% (strong recommendation).
- For acute hypoxemic respiratory failure despite conventional O2 therapy, use HFNC (weak recommendation).
- In acute hypoxemic respiratory failure, used HFNC over NIPPV (weak recommendation).
- If HFNC not available and no urgent indication for intubation, trial NIPPV with close monitoring (weak recommendation).
- No recommendation regarding use of helmet NIPPV compared with mask NIPPV.
- Recommend close monitoring for worsening of respiratory status (best practice).
- Use low tidal volume ventilation ($V_t$ 4-8 mL/kg) (strong recommendation).
- Target plateau pressures ($P_{plat}$) of < 30 cm H2O (strong recommendation).
- For moderate to severe ARDS, use higher PEEP strategy (weak recommendation).
- For ARDS, use conservative fluid strategy (weak recommendation).
- For moderate to severe ARDS, use prone ventilation for 12 to 16 hours (weak recommendation).
- For moderate to severe ARDS:
  - Use intermittent boluses of neuromuscular blocking agents over continuous infusion (weak recommendation).
  - If persistent ventilator dyssynchrony, use continuous NMBA infusion for up to 48 hours (weak recommendation).
- Do not routinely use inhaled nitric oxide (strong recommendation).
- In severe ARDS and hypoxemia, trial inhaled pulmonary vasodilator; if no rapid improvement, treatment should be tapered off (weak recommendation).
- For hypoxemia despite optimizing ventilation, use recruitment maneuvers (weak recommendation).
- For recruitment, do not use staircase (incremental PEEP) recruitment maneuvers (strong recommendation).
- In refractory hypoxemia despite optimizing ventilation, rescue therapies, and proning, use venovenous ECMO (weak recommendation).
Appendix 3: Surviving Sepsis Campaign: Guidelines for the Management of COVID-19

IV. COVID-19 Therapy

- In respiratory failure (without ARDS), do not routinely use systemic corticosteroids (weak recommendation).
- In ARDS, use systemic corticosteroids (weak recommendation).
- In respiratory failure, use empiric antimicrobials/antibacterial agents (weak recommendation).
- For fever, use acetaminophen for temperature control (weak recommendation).
- Do not routinely use IVIG (weak recommendation).
- Do not routinely use convalescent plasma (weak recommendation).
- In critically ill adults:
  - Do not routinely use lopinavir/ritonavir (weak recommendation).
  - Insufficient evidence on the use of other antiviral agents.
- Insufficient evidence on the use of recombinant rIFNs.
- Insufficient evidence on the use of chloroquine or hydroxychloroquine.
- Insufficient evidence on the use of tocilizumab.
